## **ABSTRACT**

**MADRAZO, RACHEL S. Influence of Temperature and Relative Humidity to Coffee Pests and their Natural Enemies** Undergraduate Thesis, Bachelor of Science in Agriculture major in Crop Science, Cavite State University, Indang, Cavite, June 2019.  
Adivser: Dr. Evelyn O. Singson

The study was conducted at two locations: Non-shaded and shaded areas at the National Coffee Research Development and Extension Center (NCRDEC). This study was conducted for 10 months, from June 2018 to March 2019. This study aimed to: identify the different insect pests and natural enemies of coffee in non-shaded and shaded areas in the coffee plantation; determine infestation rate of coffee pests in non-shaded and shaded areas; and determine the effect of temperature and relative humidity on coffee pests and their natural enemies

The insect pests collected and observed belong to order Hemiptera (green coffee scale and aphids). Coleoptera (beetles), Lepidoptera (butterflies and moths), Orthoptera (grasshopper), and Diptera (flies). Meanwhile, natural enemies commonly belong to order Hymenoptera (Wasps) and Coleoptera (Malaysian lady beetle). Infestation rate of common insect pests show that Coffee berry borer is higher in non-shaded area while coffee green scale is higher in shaded area. The result of the study show that temperature has significant influence on the number of insect pests. The statistical analysis reveal that for every increase per unit of temperature, there is a double increase in species of the insect pests. However, relative humidity is not an indicator of population of natural enemies and insect pests

## **INTRODUCTION**

Coffee is the second internationally transacted commodity in the world next to petroleum oil (Bongase, 2017). It is primarily cultivated in the equatorial regions of Central and South America, Africa and Southeast Asia. Coffee plants are now raised in more than 70 countries. In the Philippines, coffee farmers usually own a land with an average size of 1 to 2 hectares. The most common coffee species used is *Coffea canephora* which contributes to over 75% of production followed by *C. arabica*, *C. liberica* and *C. excelsa*. The total land production allocated in the Philippines for coffee production is 113,738 hectares. SOCCSKSARGEN has the highest portion with 26,731 hectares. Meanwhile CALABARZON produced 2,272 metric tons of coffee beans in 2015 and increased in 2016 with 2,817 metric tons. Coffee is the most traded tropical crop that is being exported throughout the world. However Craparo *et al.* (2015) and Bongase (2017) concluded that the harsh effects of climate change lowered the
